**Abstract**

The distribution of the three Italian species of Rhysodidae was reviewed by re-examining published data, museum conserved and newly collected specimens. *Rhysodes sulcatus* chronogeometry encloses a large majority of old findings and only two recently confirmed active populations are recorded after the year 2000. *Omoglymmius germari* shows a similar picture, with only one recent record (2018) in the Pollino National Park (Basilicata) but a small number of active populations after 2000. *Clinidium canaliculatum* populations are in a much better conservation status, with about 50 new sites detected after 2000 in the Sila National Park. Threats and research/monitoring needs have been discussed for each species and new IUCN status proposed for Italian populations: Critically Endangered (CR) for *Rhysodes* and *Omoglymmius*, Near Threatened (NT) for *Clinidium*.

**Key words:** IUCN, conservation status, EU Habitats Directive, chronogeometry, biodiversity conservation.

**Introduction**

The beetles of the family Rhysodidae are represented by more than 350 species worldwide, mainly distributed in tropical forests, where they live depending on the ameboid stages of Myxomycetes growing in dead wood (Bell 1998). They are placed within the suborder Adephaga as a separate, primitive, family by several authors, or, in more recent times, also as a part of Carabidae, as a subfamily, tribe or subtribe. In this work we follow the proposal by Makarov (2008), who places the Rhysodids as an independent family of Geodaphaga with a probable Archostematan ancestor, based on the similarity of larval morphologies.

As saproxylic components of the food web (Speight 1989) the Rhysodids follow the dynamics of tree aging and are involved in the processes of fungal decay of wood and nutrient recycling in natural ecosystems (Burakowski 1975; Alexander 2008). They are particularly affected by inappropriate forest management, habitat loss, and deterioration of forest quality. At European level only one species, *Rhysodes sulcatus* Fabricius, 1787, is listed in the annexes II and IV of Council Directive 92/43/EEC ("Habitats")

as well as by the Bern Convention (annex II), and is also listed in the IUCN red list of Threatened species (Nieto & Alexander 2010), classified as EN (Endangered) in the EU 27 and as DD (Data Deficient) for the whole continent.

Two other Rhysodid species are recorded from Italy, *Clinidium canaliculatum* (O. G. Costa, 1839) and *Omoglymmius germari* (Ganglbauer, 1891), both listed as VU (Vulnerable) (Italian populations: Carpaneto et al. 2015) and DD in Europe (Nieto & Alexander 2010). Despite the importance of Rhysodids for biodiversity conservation, data about their distribution in Italy are still fragmentary and often only based on old museum material; also more recent records are mostly found in grey literature rather than obtained during targeted research campaigns. This status of knowledge is even more inhomogeneous because of the cryptic way of life of the adults and especially of the larvae, and by the progressive rarefaction of old growth forests and of the wood necromass in managed ones.

This paper is an attempt to assess the distribution and preservation status of the Rhysodid beetle species across Italy, with the aim to facilitate research and monitoring in view of Natura 2000 reporting and future conservation measures.

## Materials and methods

We focused on both recent and historical literature regarding the distribution of the three species, and examined several museum collections. Further data have been obtained by direct collecting in Southern Italy during monitoring surveys in the frame of the Natura 2000 IV Report to be due in the past March, 2019. For each species, records have been listed and georeferenced from North to South (In “Results” below and in Table 1). The geographic coordinates have been reported in the UTM system, WGS84; number of decimal places vary according to the accuracy of labels. In the case of historical records, the GPS coordinates are only approximate. In Table 1 the distribution data have been ordered on chronological basis: after 2000 (green); between 1970 and 2000 (yellow); before 1970 (grey). Acronyms of Italian provinces follow the official list available at <https://www.comunecitta.it/sigle-province-italiane>.

Collections examined are indicated by the abbreviations below:

<b>MGE</b>	Museo civico di Storia Naturale “G. Doria”, Genoa. Collections: A. Dodero, G. Binaghi.
<b>MFI</b>	Museo Zoologico “La Specola”, Florence.
<b>MZUR</b>	Museo di Zoologia dell’Università di Roma, Rome: Coll. M. Cerruti.
<b>MCZR</b>	Museo Civico di Zoologia di Roma. Collections: P. Luigioni, F. Rasetti, D. Vita.
<b>MSNC</b>	Museo di Storia Naturale della Calabria, University of Calabria, Sect. of Entomology. Collection: P. Brandmayr.
<b>FA</b>	Private collection: F. Angelini, Via Imperiali, 203 - 72021 Francavilla F. (Brindisi).
<b>AVT</b>	Private collection: A. Vigna Taglianti, at present preserved in MZUR.

vanna, labeled “622. *Rhysodes / sulcatus* Fab. / M° Amiata / [Mt. Amiata, Grosseto province], abetina [fir forest] del Pigel= / leto.”. In our opinion a wrong locality, due perhaps to a label exchange with a lost specimen of *Rhysodes*. *C. canaliculatum* is reported by Magrini & Vanni (2001: 102) from Tuscany in six localities in the provinces of Pistoia, Florence, Arezzo, Grosseto, but not from the Amiata Mount. Magrini (personal communication, 2008) informed us that the data in fact concern the distribution of *Platyderus canaliculatus* [= *neapolitanus*; Carabidae], being the entire page a misprint.

## Analysis of geographic distributions in Italy

### *Rhysodes sulcatus* (Fig. 1)

The large amount of gathered data supports a first chrono-geonomic analysis of the three Rhysodids in Italy. In Fig. 1 the known localities have been ordered based on collection time. The historical distribution (before 1970: Luigioni 1929; Papini 1962; Raffray (MZUR); M. Barajon (MGE)), indicates *Rhysodes sulcatus* only from Lombardy, Tuscany, Latium, Abruzzi, Campania, Apulia and Basilicata). During more than a century this species has been collected from 15 localities in seven Italian regions, but in the period 1970-2000 only in two ones: Emilia-Romagna and Apulia. After 2000 the findings also concentrate in only two regions: Emilia Romagna and Abruzzi. The general conservation status of *R. sulcatus* in Italy looks extremely precarious, and until now its presence was not confirmed at any of the historical sites. Scattered populations seem to

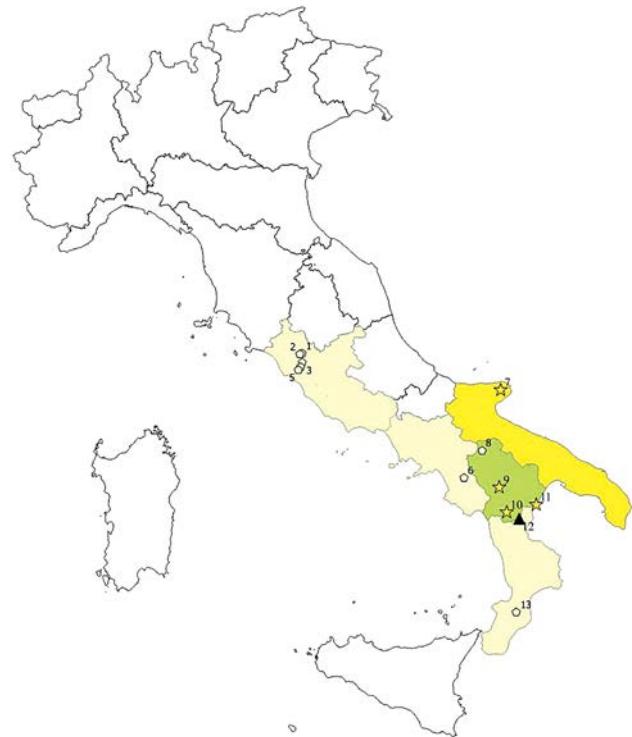

**Fig. 1** – Historical and contemporary distribution of *Rhysodes sulcatus* in Italy. Recent records (after 2000) are represented by solid triangles; records 1970–2000 by stars; records before 1970 by pentagons. Light green: regions in which the species was collected only before 1970. Yellow: only records before 2000 available. Dark green: data after 2000.

survive only along the Apennine chain of Central Italy in some beech forest “sanctuaries” like the old growth forest of the Gran Sasso National Park (Di Santo & Biscaccianti 2014) or the “Foresta della Lama” in the National Park “Foreste Casentinesi” on the Romagna-side of the chain (Ceccolini & Norbiato 2015). Consequently, in Italy *R. sulcatus* remains at the moment an endangered species, it shows no signs of reprise and it is highly probable that several of the historical populations are extinct since long time. This Euro-Siberian beetle seems a little better conserved in France (Brustel & Gouix 2011), but on the whole its actual presence in Europe is noticeably rarefied in most recent times (Bussler et al. 2005; Vrezec 2007; Konvička & Čížek 2015; Šag et al. 2016). Speight (1989) documented the extinction of this rare beetle in western and middle Europe and proposed it as one of the most reliable indicators of forests of international importance.

#### *Omoglymmius germari* (Fig. 2)

Fig. 2 recapitulates the chronogeometry of the species in Italy. During over 100 years the beetle has been recorded in 13 localities inside 5 Italian regions, but only one finding dates after the year 2000, in an ancient traditional silver fir forest of the Pollino National Park (Basilicata region). In the three decades 1970–2000 some more records

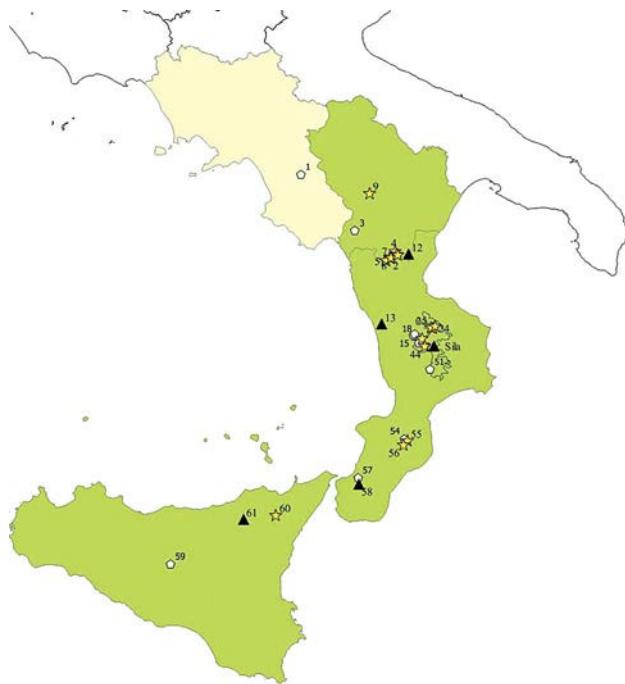

**Fig. 2** – Historical and contemporary distribution of *Omoglymmius germari* in Italy. Symbols and colors as in Fig. 1.

are known from Basilicata and from Apulia, in the old forest of the Gargano promontory. In the remaining regions (Latium, Campania and Calabria) all findings date before 1970, in some cases they are over 100 years old. This beetle is distributed in Southeastern Europe, Anatolia, Caucasian countries, Azerbaijan, Iran (Northern Khorasan), and seems to be strongly declining or at least rarefied in several European countries (Konvička & Čížek 2015; Šag et al. 2016; Bekchiev 2010; Bussler et al. 2005). Apparently lacking in France (Brustel & Gouix 2011). Its ecological preferences also include flatland habitats around rivers and it was also recorded from poplar formations like the *Populetum nigro-albae* (Šag et al. 2016). In the Pollino National Park it was collected in a centuries-old silver fir forest used by local inhabitants (of the village of Alessandria del Carretto) for a spring feast in which a maypole tree is erected (“Festa della Pita”).

#### *Clinidium canaliculatum* (Figs 3, 4)

This species exhibits a more restricted distribution, and its geographic range covers exclusively Southern Italy and Greece, from Sicily to Taygetos in Morea, and is considered among the vulnerable Mediterranean endemites (García et al. 2018). In more than 100 years it has been recorded from 61 sites of four Italian regions. Recent findings are located in Sicily and especially in Calabria, in the years 1970–2000 also in Basilicata (Fig. 3). The only known record from Campania (Mt. Alburno) is very old and has not

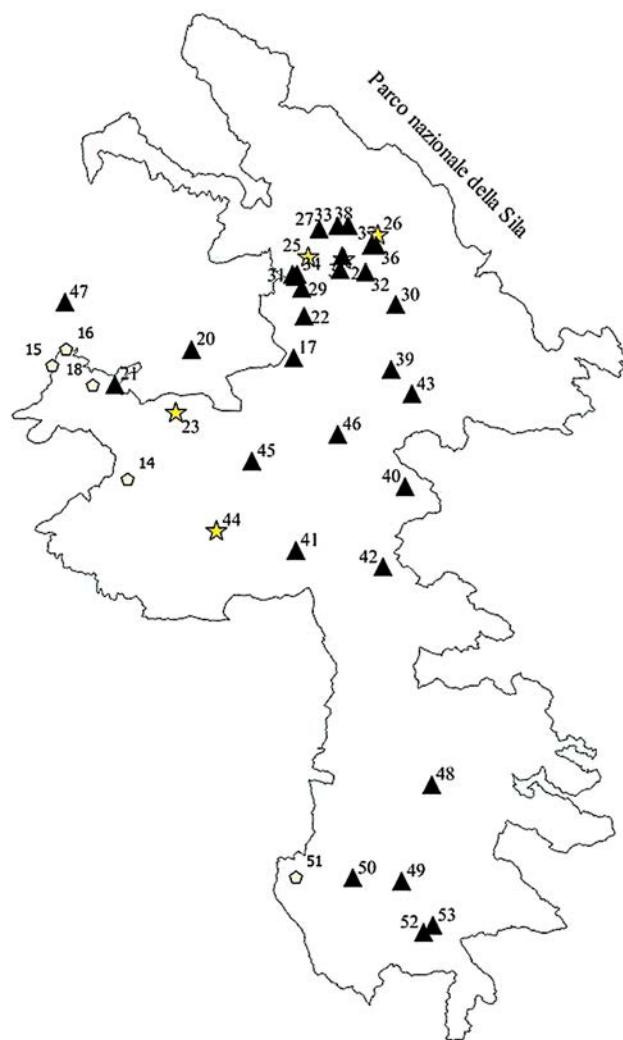

**Fig. 3** – Historical and contemporary distribution of *Clinidium canaliculatum* in Italy. Symbols and colors as in Fig. 1.

reconfirmed since today. Fig. 4 represents the distribution of *C. canaliculatum* at smaller scale in the Sila National Park in central Calabria. Here the species was practically absent in the years before the last millennium end, probably because of precipitation scarcity. It reappeared in the years around 2010 after a long period of dryness and is now easy to find on decaying logs and snags of *Pinus nigra calabrica*. After a thorough ecological study of saproxyllic beetles performed in the Sila forest landscape, Mazzei et al. (2018) proposed this species as “biodiversity indicator” of forest ecosystems with high conservation value. The biology of the beetle remains anyway poorly investigated.

## Conclusions

The Rhysodids are poorly mobile and flightless beetles strictly bound to decaying wood where they feed on slime mold plasmodia (previously named Myxomycetes, now considered a phylum of the Protozoa, called Myxostelida). *Rhysodes* and especially *Omoglymmius* seem frequent on a wide variety of trees, and despite a larger distribution area in Europe, their conservation status in Italy is very unsatisfactory. The first species is considered a relic of primeval forests, very sensitive to disturbances to forest ecosystems, present throughout Europe in the past, now extinct in many European countries (Sienkiewicz 2017). Our assessment shows that the Italian populations of both species became extremely rarefied in the last decades, and their survival seems granted only in old growth forests

**Fig. 4** – Historical and contemporary distribution of *Clinidium canaliculatum* in the Sila National Park. Recent records (after 2000) are represented by solid triangles; records between 1970–2000 by stars; records before 1970 by pentagons.

maintained since centuries and characterized by uninterrupted habitat continuity. The main threats are certainly the removal of large deadwood masses, especially logs, from humid forest sites, but we could not exclude an effect of the decreasing precipitations connected to the climate change. *Clinidium* on the contrary inhabits almost exclusively coniferous forests, mainly those with *Abies alba* and *Pinus nigra calabrica*, where it is frequently found aggregated in small groups under bark or inside the red-decaying wood. In our experience it strongly depends on wood humidity and this could explain the absence or rarity of the species during drought periods, as observed also for *Cucujus cinnaberinus* (Coleoptera Cucujidae) in the Sila National Park (Mazzei et al. 2011b). Nevertheless, the conservation status of this subendemic species seems by far less alarming, as indicated by the increasing population density and occurrence observed in the last ten years

in the Sila N. P. (Mazzei et al. 2018). In conclusion, the following conservation status of Rhysodids should be acknowledged for Italy:

### ***Rhysodes sulcatus* (Fabricius, 1787)**

**International Law:** protected by the European Habitats Directive (annex II of Council Directive 92/43/EEC)

**Domestic Law:** included in the IUCN red list as Data Deficient (DD), IUCN Red List of Threatened Species, Méndez et al. 2010; Endangered (EN) B2ab (iii), Red List of Italian Saproxylic Beetles, Audisio et al. 2014. Endangered (EN), B2ab (iii), Carpaneto et al. 2015. Not Evaluated (NE), García et al. 2018.

### **New proposal for Italy: Critically Endangered (CR)**

In order to determine the current distribution of *Rhysodes sulcatus* in Italy, inventories should be carried out covering old positions and sites where, according to current data, proper habitat conditions still exist.

### ***Omoglymmius germari* (Ganglbauer, 1891)**

**Domestic Law:** Species protection - strict protection (species that require active protection) IUCN. Threat Category IUCN: Data Deficient (DD), IUCN Red List of Threatened Species, Méndez et al. 2010; Vulnerable (VU), B2ab (iii) DD PR, Audisio et al. 2014. Not Evaluated (NE), García et al. 2018.

### **New proposal for Italy: Critically Endangered (CR)**

Research recommendation: as for *R. sulcatus*.

### ***Clinidium canaliculatum* O.G. Costa, 1839**

**Domestic Law:** Species protection - strict protection (species that require active protection) IUCN. Threat Category IUCN: Vulnerable (VU) IUCN Red List of Threatened Species, Brustel et al. 2017; Vulnerable (VU), B2ab (iii) DD PR, Audisio et al. 2014; Vulnerable (VU), B2ab (ii,iii), endemic, García et al. 2018. Evaluated as indicator of forest ecosystems with high conservation value (Mazzei et al. 2018).

### **New proposal for Italy: Near Threatened (NT)**

Research recommendation: periodic monitoring for the aims of the Natura 2000 network; careful visual census in older sites if proper habitat conditions still existing.

**Acknowledgements** – The authors wish to thank the President, Mrs Prof. Sonia Ferrari, and the Director, Dr. Giuseppe Luzzi of the Sila National Park for financial help and research permissions gently granted along several years. They feel also grateful to the President and the Director of the Pollino National Park for research permissions received in the year 2018.
