(RECEIVED 11 MARCH; RECEIVED IN REVISED FORM 25 MARCH; ACCEPTED 26 MARCH)

**ABSTRACT** – The present paper aims to show the importance of analyzing plant macroremains from urban excavations. Organic materials preserved below the historical city in waterlogged conditions are a fundamental resource, and the study of seeds and fruits gives a good contribution to historical and archaeological research. Archaeobotany in urban contexts provides important results when the examined material comes from several excavations that “photograph” the territory over quite a long period. An overview of archaeobotanical analyses carried out on material from archaeological sites of Modena (Emilia-Romagna), from the 2<sup>nd</sup> century BC to the 6<sup>th</sup> century AD, made by the Laboratory of Palynology and Palaeobotany of the University of Modena and Reggio Emilia, is presented. The floristic list of seed/fruit analyses result is reported and interesting subject matters are tackled concerning both cultivated/cultivable plants (fruits and nuts, vegetables/aromatics/spices/medicinal plants, fibre and oil plants, cereals and pulses, flowers and other ornamental plants) and wild plants of no obvious use, together with wetland plants which are rare and endangered species in Emilia-Romagna today.

**KEYWORDS:** PLANT MACROREMAINS, ROMAN PERIOD, MODENA, NORTHERN ITALY, ETHNOBOTANY, LANDSCAPE

## INTRODUCTION

The importance of the analysis of organic remains from urban excavations is well known (e.g. Orser, 2002; Majewski & Gaimster, 2009).

Concerns that previously limited the substantial contribution of Archaeobiology only to studies of prehistoric sites have been overcome, expanding the potentialities of this discipline also to the historical period (e.g. Renfrew, 1973). In particular, innovations in techniques and in the approach of Archaeobotany (e.g. Pearsall, 2008; Cappers & Neef, 2012) have allowed a wider application for all kinds of investigation, from plant domestication problems (e.g. Zohary & Hopf, 2004) to reconstruction of garden history (e.g. Moe et al., 1994; Morel et al., 2006). The organic materials preserved below the historical city in waterlogged conditions are a fundamental resource, also for their potential biomolecular research (Kenward & Hall, 2008). Ancient DNA analyses have become increasingly important, with an

exponential trend in recent years, and waterlogged plant materials from archaeological sites offer many opportunities to be explored, despite their limits (Schlumbaum et al., 2008). Moreover, charred remains can also be found in urban deposits; these provide additional information especially about plants related to human alimentation, in particular cereals and legumes, which are often found only in these conditions (Bandini Mazzanti et al., 2005a). Archaeobotany in an urban context provides important results when the material examined comes from several excavations that “photograph” the territory over a quite long period. There are some significant examples of recent investigations concerning several European cities: a) Agriculture and food in Lleida (Catalonia, Spain) from the Roman Age (2<sup>nd</sup> century BC) to the Islamic period (11<sup>th</sup> century AD) (Alonso Martinez, 2005); b) Ethnobotany in Ferrara (Emilia Romagna, Italy) between the Middle Ages and Renaissance (13<sup>th</sup> – 15<sup>th</sup> centuries AD) (Bandini Mazzanti et al., 2009; Bosi et al., 2009a); c) Environment and “useful” plants in the

Middle Ages (13<sup>th</sup> – 14<sup>th</sup> centuries AD) in Prague (Czech Republic) (Beneš et al., 2002); d) Medieval food traditions (13<sup>th</sup> – 17<sup>th</sup> centuries CE) in Northern Europe (Karg, 2007). The reconstruction of an urban area unquestionably depends on the history of the humans who transformed it over time. Moreover, human history is always linked to the “cultural history” of the plants used for food, medicine and much more (Prance & Nesbitt, 2005). In archaeobotanical research, the study of seeds and fruits can support historical and archaeological research providing important information from taphonomic understanding of deposits to information on agriculture and economics, human diet, the esoteric sphere, as well on the environment surrounding the site (e.g. Bandini Mazzanti et al., 2005b).

This contribution refers to the study case of *Mutina* (now Modena), a Roman colony founded in 183 BC, important both for military-strategic and economic reasons, described by Cicero as a “*firmissimam et splendidissimam populi romani coloniam*”. Thanks to the collaboration with the Superintendence of Archaeological Heritage of Emilia Romagna, numerous archaeological sites of the Roman Period which have come to light in Modena have been investigated, both with carpological (Rinaldi, 2010; Bosi et al., 2011), palynological and xilo-anthracological analyses

(Venezia, 2003/2004 and unpublished data).

The information provided by botanical remains from the Roman sites of Modena has allowed the interpretation of palaeoethnobotany, history and knowledge of flora and vegetal landscape of the Modena area during the Roman Age, which are aspects totally in accord with the aims of Archaeobotany (e.g. Van Zeist et al., 1991; Hastorf, 1999).

## MATERIALS AND METHODS

Samples were collected and studied from different layers belonging to four sites (Tab. 1) within the *Mutina* settlement. The sites date from the 2<sup>nd</sup> century BC to the 6<sup>th</sup> century AD, almost from the foundation of the Roman city to its decline. They were excavated in Modena, both in the present-day town-centre and in the surroundings: three sites (1, 2, and 3) relate to the ancient centre of the Roman town of *Mutina* and one (4) to the immediate suburbs (Fig. 1).

Searching for macroremains (a total of over 1200 l of soil – Tab. 1) were soaked in water and then washed through a bank of three sieves with 10, 0.5 and 0.2 mm meshes.

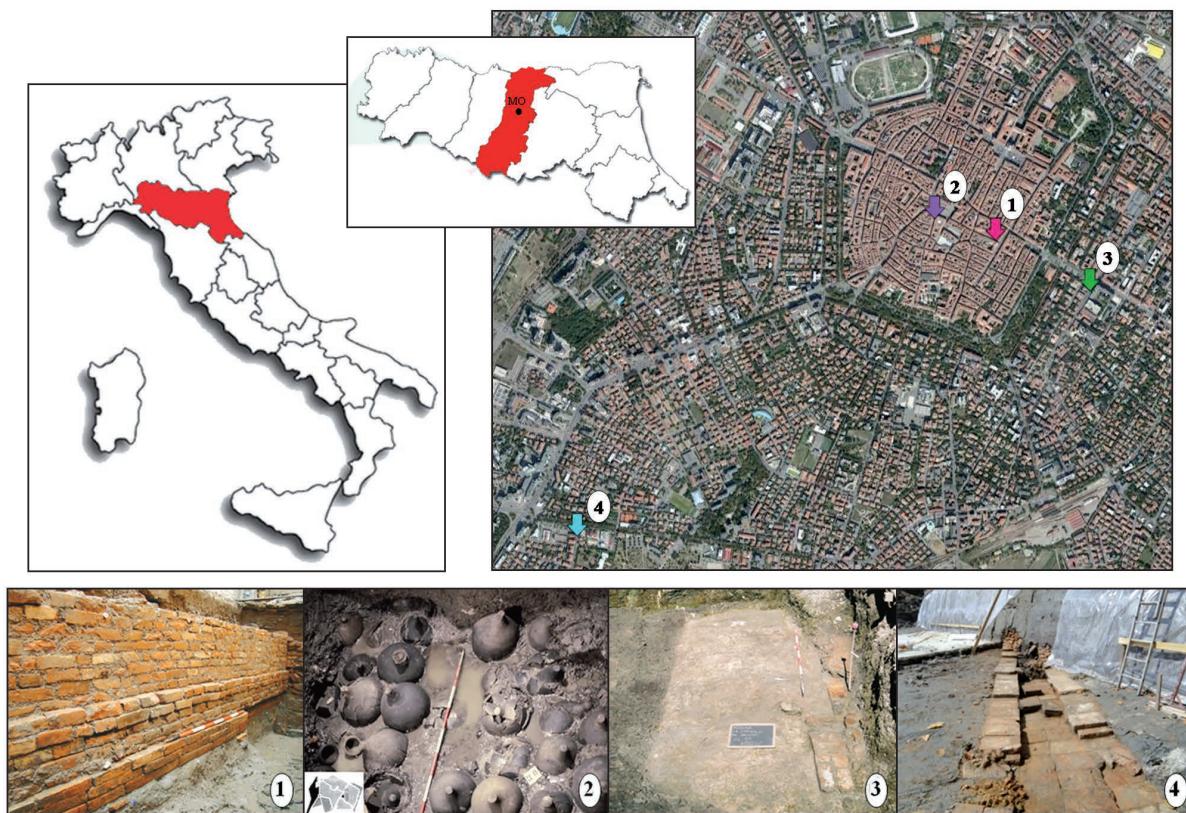

Fig. 1. - Location of the four investigated archaeological sites of ancient *Mutina* in present-day Modena, Emilia Romagna.  
At the bottom, photographs of the site excavations.

Table 1. - Main features of the four investigated archaeological sites of ancient *Mutina*.

<b>carpological sum</b>	10310	167012	17901	17071
<b>references</b>	Rinaldi, 2010	Rinaldi, 2010; Venezia, 2003/2004; Bosi et al., 2012	Rinaldi, 2010; Bosi et al., in litteris	Rinaldi, 2010; Bosi et al., in litteris and unpublished data

§ - s/f = seeds/fruits; w = woods; wt = wood tools; c = charcoal; p = pollen (analysis in progress).

Seeds and fruits from each fraction were sorted and identified (Tab. 2) using a Leica Wild M10 stereomicroscope (up to 80x magnification) and the reference collection, atlases and keys (Beijerinck, 1947; Scurti, 1948; Kiffmann, 1958; Berggren, 1969, 1981; Delorit, 1970; Montégut, 1972; Renfrew, 1973; Häfliger & Brun-Hool, 1981; Frank & Stika, 1988; Jacquat, 1988; Schoch et al. 1988; Jacomet et al., 1991; Viggiani & Angelini, 1991, 2005; Hubbard, 1992; Young & Young, 1992; Davis, 1993; Anderberg, 1994; Spjut, 1994; Pignotti, 1998; Cappers et al., 2006; Nesbitt, 2006). SEM was used for problematic identifications (e.g. *Cucumis melo*). For

scientific plant names several references were used (Tutin et al., 1964 - 93; Pignatti, 1982; Alessandrini et al., 2010). Figure 2 shows photos (taken with a Nikon Digital Sight DS-5M photographic camera) of selected carpological findings; the measurements (length or greater extent) were taken with the software ImageJ. For site 2, we show the results of previous analyses of charcoal, wood and wooden tools (Venezia, 2003/2004) (Tab. 3); for site 4, xilological analyses were carried out (by Marco Marchesini, Superintendent to Archaeological Heritage of Emilia Romagna) though just at a preliminary level (Tab. 3).

In this contribution only the qualitative data of plant macroremains are reported, deferring to previous research (Rinaldi, 2010; Venezia, 2003/2004) and to further work for quantitative data.

Pollen data were not reported because the investigations on the sites where they are present (1 and 4) are still ongoing.

## RESULTS AND DISCUSSION

In the four sites, a total amount of 200,000 carpological remains have been isolated (Tab. 1 - Rinaldi, 2010) together with more than 500 xilo-anthracological remains (Venezia, 2003/2004 and unpublished data), mainly waterlogged (several charred), corresponding to more than 400 taxa (Tab. 2). This list is quite long, especially if compared with the list of 175 taxa obtained from the study of about 80 Medieval sites in Northern Europe (Karg, 2007). Paleoecological reconstructions (Rinaldi, 2010) show the presence of wetland environments, peculiar to the Modena area (such as water springs, canals, trenches and wet

grasslands). These features are reported by *Appianus* (2<sup>nd</sup> century AD) in quotations relating to the Civil War, which describe the landscape of Modena as being rich in water, powered by fountains with land cut across by ditches (Calzolari, 2008). Concerning this particular aspect of the wetlands, a study comparing Modena in the Roman Period and in the Middle Ages (Bosi et al., *in litteris*) is in progress. Research has revealed a floristic list (Tab. 2) numerically superior than the one available (almost 300 taxa) for the over 30 Roman sites previously studied from a carpological standpoint in Emilia Romagna (Rinaldi, 2010). The floristic list of the Roman Period, compared with the present floristic list of planital plants of the Province of Modena (Alessandrini et al., 2010), corresponds to about 1/3 of the

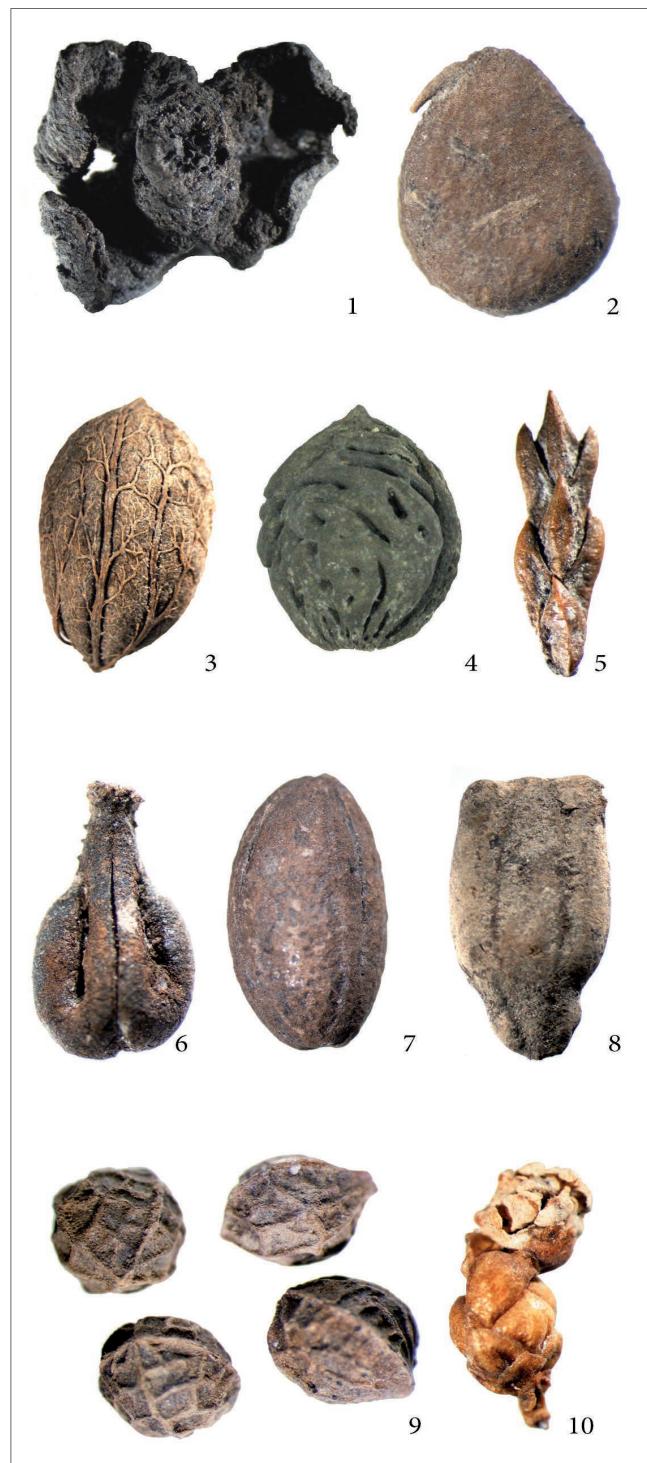

Fig. 2. - Photos of some carpological records: 1) *Dyospyros lotus* (calyx – 1.8 cm - charred); 2) *Morus nigra* (endocarp – 3.4 mm); 3) *Olea europaea* (endocarp – 1.3 cm); 4) *Prunus persica* (endocarp – 2.1 cm); 5) *Cupressus sempervirens* (twig – 5.8 mm); 6) *Vitis vinifera* subsp. *vinifera* (pip – 6.7 mm); 7) *Cornus mas* (endocarp – 1.1 mm); 8) *Lagenaria siceraria* (seed – 14.5 mm); 9) *Celtis australis* (endocarp – 3.2 mm); 10) *Taxus baccata* (male flower – 8.5 mm) (photos: R. Rinaldi & G. Bosi).

latter. The number of taxa shows the great biodiversity present in *Mutina*: the carpological remains cannot be spread for a great distance, the scarce resistance to degradation shown by seeds and fruits even belonging to important families (e.g. Poaceae, Liliaceae s.l.) is known, and all the sites here studied are situated in the town area. Such floristic richness is also supported by the findings of numerous wild species worthy of attention, some of them unknown in earlier sources, others which disappeared during the XX century and many considered rare. This floristic list, together with archaeobotanical reconstructions of environments which have now virtually disappeared, can support the protection and maintenance works of the few surviving “natural” sites, especially wetlands.

Concerning ethnobotanical information, site 1 (a Roman channel dating from the early Roman Empire) provides most of the findings of cultivated plants. This site shows the best evidence of the prosperity of the town. The principal findings of this study are: 1) availability of particular plant products, even imported, such as the fruits of *Diospyros lotus*; 2) availability of luxury goods, such as olives, pomegranates and various condiment plants, including coriander; 3) availability of luxury goods, not fundamental for survival, such as abundant and diverse fruits; 4) evidence of early cultivation of fruit or vegetable species, perhaps recently arrived in the territory, in particular *Prunus persica*, *Cucumis melo*, *Lagenaria siceraria*, *Morus nigra*; 5) evidence of fertile land with a large range of crops both woody and herbaceous. Among these species, others are present that could be used for textile/dyeing purposes and to raise sheep for wool (for which *Mutina* was famous - Calzolari, 2008), and in particular textile plants, such as flax and hemp, together with dyeing plants such as weld, safflower and madder; 6) evidence of ornamental plant species, such as *Myrtus communis*, *Cupressus sempervirens* and *Tamarix*, as well as European nettle tree (*Celtis australis*), plane tree and silver birch. Elsewhere in Emilia Romagna, such prosperity and luxury are indicated only in a rubbish pit (dating from the first half of the 15<sup>th</sup> century AD) that collected refuse from the Este ducal palace of Ferrara at its moment of greatest splendour (Bosi et al., 2009b).

From the data obtained, some interesting aspects related to site chronology can be shown, even considering the taphonomic diversity of the deposits. In the Roman Republican Period distinctive features of affluence are already present in the city, indicated by ornamental plants such as myrtle, cypress, plane tree and many testimonies of food crops such as walnut, olive tree, vine, cereals. In the Late Roman Period it is possible to observe the evidence of some ornamental species and especially of crops, in particular woody crops such as vine, walnut, cherry tree, fig, peach, which are the first that can be affected by a change in stability. Among these, vine, walnut and cherry tree are

the cultural heritage in the territory of Modena and they have apparently survived even the most critical periods successfully.

Given the lasting evidences of “noble” cereals, such as wheat and barley, and the absence/scarcity of minor cereals, it appears that agriculture continued even during the decay of the Empire, probably concerning the surface area utilized less than before, but not degraded. This fact is probably related to the fertility of the soils surrounding the town and to the abundance of water for irrigation, which is still present after centuries of exploitation. This peculiarity of Emilia is important, especially when we consider the transition towards more rustic crops that took place from the late Roman to early Middle Ages, particularly from a historical-literary viewpoint.

## ACKNOWLEDGEMENTS

The authors would like to thank Donato Labate, Marco Marchesini and the Superintendence for Archaeological Heritage of Emilia Romagna. They are also grateful to Luisa Forlani and Maria Concetta Venezia for the xylo-anthracological study and to Prof. Andrea Mary Lord for the revision of the original English text.
